

ON THE SPEED OF SPREAD FOR FRACTIONAL REACTION-DIFFUSION EQUATIONS

HANS ENGLER

ABSTRACT. The fractional reaction diffusion equation $\partial_t u + Au = g(u)$ is discussed, where A is a fractional differential operator on $\mathbb{R}$ of order $\alpha \in (0, 2)$, the C^1 function g vanishes at $\zeta = 0$ and $\zeta = 1$ and either $g \geq 0$ on $(0, 1)$ or $g < 0$ near $\zeta = 0$. In the case of non-negative g , it is shown that solutions with initial support on the positive half axis spread into the left half axis with unbounded speed if $g(\zeta)$ satisfies some weak growth condition near $\zeta = 0$ in the case $\alpha > 1$, or if g is merely positive on a sufficiently large interval near $\zeta = 1$ in the case $\alpha < 1$. On the other hand, it is shown that solutions spread with finite speed if $g'(0) < 0$. The proofs use comparison arguments and a new family of travelling wave solutions for this class of problems.

1. INTRODUCTION

The scalar reaction-diffusion equation

$$(1) \quad \partial_t u(x, t) - \partial_x^2 u(x, t) = g(u(x, t))$$

has been the subject of long study, beginning with the celebrated paper [11]. The authors of [11] proposed this equation, with g positive and concave on $(0, 1)$ such that $g(0) = g(1) = 0$, as a model for a population that undergoes logistic growth and Brownian diffusion. If $u(x, 0) = H(x)$, the Heaviside function, and $g(u) = u - u^2$, the equation in fact has an exact probabilistic interpretation, see [14]. For this problem, it is known that solutions approach a wave profile ψ in the sense that

$$u(x + m(t), t) \rightarrow \psi(x) \quad (t \rightarrow \infty)$$

where $m(t)$ is the median, $u(m(t), t) = \frac{1}{2}$. It turns out that $m(t) = c^*t + O(\log t)$ for a suitable asymptotic finite wave speed c^* . Larger asymptotic speeds are only possible if the initial data are supported on $\mathbb{R}$. A more general result, given in [2], implies that there is a critical speed c^* such that for fairly general initial data $u(\cdot, 0)$ that are non-negative and supported on $(0, \infty)$,

$$(2) \quad \lim_{t \rightarrow \infty} \limsup_{x < -ct} u(x, t) = 0$$

whenever $c > c^*$ and

$$(3) \quad \lim_{t \rightarrow \infty} \liminf_{x > -ct} u(x, t) = 1$$

whenever $c < c^*$. If u denotes a quantity that is to be avoided and whose spread is governed by (1), a runner may escape from it by running to $-\infty$ at a speed $c > c^*$, but this quantity will catch up with and engulf her if her speed is $c < c^*$.

Equation (1) was also derived in [1] to describe antiphase domain coarsening in alloys. In this situation, $g(0) = g(1) = g(u^*) = 0$ for some $u^* \in (0, 1)$, and $g < 0$ on $(0, u^*)$, $g > 0$ on $(u^*, 1)$. In this case there exists exactly one wave speed c^* with associated wave profile. In particular, (2) still holds for this c^* . The first of the two cases (the KPP case) corresponds to "pulled" fronts (the state $u = 0$ is unstable) while the second case (the Allen-Cahn case) results in a "pushed" front (the state $u = 0$ is stable). More on these two fundamentally different situations may be found in [8] and the references given there. A vast range of applications leading to related models is discussed in [9].

The purpose of this note is a study of the fractional reaction-diffusion equation

$$(4) \quad \partial_t u(x, t) + Au(x, t) = g(u(x, t)).$$

Here A is a pseudo-differential operator with symbol p that is homogeneous of degree $\alpha \in (0, 2]$, such that $p(-\lambda) = \overline{p(\lambda)}$ and $|p(1)| = 1$. Then we can write p in the form

$$(5) \quad p(\lambda) = e^{-i\frac{\pi}{2}\text{sign}(\lambda)\rho} |\lambda|^\alpha$$

where $\rho \in \mathbb{R}$. There will be additional restrictions on the parameter ρ in section 2. For $\rho = 0$ we obtain fractional powers of the usual negative one-dimensional Laplacian, abbreviated often by $(-\Delta)^{\alpha/2}$. There are various real variable representations of such operators, e.g. as a singular integral operator or as a limit of suitable difference operators; see [3] where this is explained in more detail. The function g is always assumed to satisfy $g(0) = g(1) = 0$. We are interested in both the KPP-case, i.e. $g(\zeta) \geq 0$ for $0 < \zeta < 1$, and the Allen-Cahn case, i.e. $g(\zeta) < 0$ for ζ near 0 and $g(\zeta) > 0$ for ζ near 1.

This class of equations has recently been proposed as a model for reaction and anomalous diffusion; see [3, 7, 12, 13, 19, 20]. It should be noted that the term "anomalous diffusion" is also used for situations in which the first order time derivative is replaced by a fractional order derivative. Another generalization of (1) consists in allowing time delays; see [17]. These further generalizations will not be discussed here.

There is strong evidence that the equation (4) does not admit traveling wave solutions if $0 < \alpha < 2$ and g is positive and concave on $(0, 1)$. Rather, numerical results in [7] and [4] suggest that for initial data that are supported on the positive half axis and increase there from 0 to 1, the median satisfies

$m(t) \sim -e^{ct}$ for some $c > 0$. In [6], the estimates

$$(6) \quad \lim_{t \rightarrow \infty} \limsup_{x < -e^{ct}} u(x, t) = 0, \quad \lim_{t \rightarrow \infty} \liminf_{x > -e^{dt}} u(x, t) = 1$$

are shown to hold for such initial data whenever $c > c^* > d$, where $c^* = g'(0)/\alpha$. Thus the asymptotic speed of spread grows exponentially. For the case where $g < 0$ on some interval $(0, u^*)$, the results in [15] and [19] suggest on the other hand that there exist wave profile solutions that move with constant speed, although no rigorous proofs are given there.

The main results of this note take the form (2) and (3). It is shown that for a large class of right hand sides g that are non-negative on $(0, 1)$, the estimate (3) holds for *all* speeds c ; that is, the speed of spread is unbounded. It is not necessary to assume that $g'(0) > 0$, and if $\alpha < 1$, g may even be zero near 0. On the other hand, if $g'(0) < 0$, then it is shown that (2) holds for some finite c , that is, there is always a bound on the speed of spread. These results are stated and proven in section 3. This is done by employing comparison arguments together with a set of travelling wave solutions that is constructed in section 2 and that may be of independent interest. Some basic existence and comparison results for (4) are sketched in section 4.

2. A CLASS OF TRAVELLING WAVE SOLUTIONS

In this section, it will be shown that cumulative distribution functions of stable probability distributions with parameters α, β lead to traveling wave solutions $u(x, t) = U(x + ct)$ of (4), for suitable functions g . A two parameter family will be constructed for each possible choice of α and ρ , one parameter being the speed c . The main contribution of this section is the characterization of the nonlinear function g that is required to make the equation hold.

Consider the probability density function $f_{\alpha\beta}$ of a stable probability distribution with index of stability $\alpha \in (0, 2)$, skewness parameter $\beta \in (-1, 1)$, scale parameter $\gamma = 1$, and location parameter $\delta = 0$, where Zolotarev's parametrization (B) (see [21]) is used for $\alpha \neq 1$ and form (C) is used if $\alpha = 1$. The characteristic function (Fourier transform) of $f_{\alpha\beta}$ then is

$$(7) \quad \lambda \mapsto e^{-|\lambda|^\alpha \omega(\lambda)},$$

where

$$\omega(\lambda) = \begin{cases} e^{-i\frac{\pi}{2}\text{sign}(\lambda)\beta(\alpha-1+\text{sign}(1-\alpha))} & (\alpha \neq 1) \\ e^{-i\frac{\pi}{2}\text{sign}(\lambda)\beta} & (\alpha = 1) \end{cases}.$$

The corresponding cumulative distribution function is denoted by $F_{\alpha\beta}$. It is known that $f_{\alpha\beta}$ is positive, infinitely differentiable, and unimodal. Also,

as $x \rightarrow \infty$, there are asymptotic representations

$$(8) \quad 1 - F_{\alpha\beta}(x) \sim \sum_{j \geq 1} c_{j\alpha\beta} x^{-j\alpha}$$

$$(9) \quad f_{\alpha\beta}(x) \sim \sum_{j \geq 1} \alpha c_{j\alpha\beta} x^{-1-j\alpha}$$

and as $x \rightarrow -\infty$

$$(10) \quad F_{\alpha\beta}(x) \sim \sum_{j \geq 1} d_{j\alpha\beta} (-x)^{-j\alpha}$$

$$(11) \quad f_{\alpha\beta}(x) \sim \sum_{j \geq 1} \alpha d_{j\alpha\beta} (-x)^{-1-j\alpha}$$

Consider now the "free" equation

$$(12) \quad \partial_t u(x, t) + Au(x, t) = 0$$

where the symbol of A is given by (5), with ρ given by

$$(13) \quad \rho = \begin{cases} \beta(\alpha - 1 + \text{sign}(1 - \alpha)) & (\alpha \neq 1) \\ \beta & (\alpha = 1). \end{cases}$$

Throughout the rest of the paper, we shall only consider operators A with symbol p in (5) for which ρ is of the form (13) for some $\beta \in (-1, 1)$. The relation (13) between β and ρ will always be assumed. Taking the Fourier transform then shows that equation (12) has the fundamental solution

$$(x, t) \mapsto W(x, t) = t^{-1/\alpha} f_{\alpha\beta}(xt^{-1/\alpha})$$

with initial data $W(x, 0) = \delta_0(x)$, the delta distribution. In particular, $W(x, 1) = f_{\alpha\beta}(x)$. There is also the special solution

$$(x, t) \mapsto V(x, t) = F_{\alpha\beta}(xt^{-1/\alpha})$$

with initial data $V(x, 0) = H(x)$, the Heaviside function. The equations hold in the sense of distributions, and the initial data are attained in this sense.

From now on, let α, β be fixed. For fixed $c \in \mathbb{R}$ and $\tau > 0$ we consider the function

$$(14) \quad U_\tau(\xi) = F_{\alpha\beta}(\xi\tau^{-1/\alpha}).$$

Set $u_{c\tau}(x, t) = U_\tau(x + ct)$, then

$$\begin{aligned} Au_{c\tau}(x, t) &= -\partial_\tau F_{\alpha\beta}((x + ct)\tau^{-1/\alpha}) \\ &= \frac{1}{\alpha} ((x + ct)\tau^{-1/\alpha-1}) f_{\alpha\beta}((x + ct)\tau^{-1/\alpha}) \end{aligned}$$

and

$$\partial_t u_{c\tau}(x, t) = c\tau^{-1/\alpha} f_{\alpha\beta}((x + ct)\tau^{-1/\alpha})$$

and therefore

$$\begin{aligned} \partial_t u_{c\tau}(x, t) + Au_{c\tau}(x, t) &= \left(\frac{1}{\alpha} \left((x + ct)\tau^{-1/\alpha-1} \right) + c\tau^{-1/\alpha} \right) \times \dots \\ &\quad \dots \times f_{\alpha\beta} \left((x + ct)\tau^{-1/\alpha} \right) \end{aligned}$$

Now $(x + ct)\tau^{-1/\alpha} = F_{\alpha\beta}^{-1}(u_{c\tau}(x, t))$ and consequently

$$(15) \quad \partial_t u_{c\tau}(x, t) + Au_{c\tau}(x, t) = c\tau^{-1/\alpha} g_0(u_{c\tau}(x, t)) + \frac{1}{\alpha\tau} g_1(u_{c\tau}(x, t))$$

with

$$(16) \quad g_0(\zeta) = f_{\alpha\beta}(F_{\alpha\beta}^{-1}(\zeta)), \quad g_1(\zeta) = F_{\alpha\beta}^{-1}(\zeta) f_{\alpha\beta}(F_{\alpha\beta}^{-1}(\zeta)).$$

Equation (15) is of the form (4), with $g(\zeta) = c\tau^{-1/\alpha} g_0(\zeta) + \frac{1}{\alpha\tau} g_1(\zeta)$.

In the case $\alpha = 1$ and $-1 < \beta < 1$, everything is explicit. Let $\kappa = \cos \frac{\pi\beta}{2}$ and $\sigma = \sin \frac{\pi\beta}{2}$. Then by results in [21],

$$\begin{aligned} F(x) &= \frac{1}{2} + \frac{1}{\pi} \arctan \frac{x - \sigma}{\kappa} \\ F^{-1}(\zeta) &= \sigma - \kappa \cot(\pi\zeta) \\ f(x) &= \frac{1}{\pi\kappa(1 + (x - \sigma)^2/\kappa^2)} \\ g_0(\zeta) &= \frac{1}{\kappa\pi} \sin^2(\pi\zeta) \\ g_1(\zeta) &= \frac{\sigma}{\pi\kappa} \sin^2(\pi\zeta) - \frac{1}{\pi} \cos(\pi\zeta) \sin(\pi\zeta) \end{aligned}$$

It remains to characterize the functions g_0, g_1 in the general case.

Proposition 2.1. *Let $0 < \alpha < 2$, $-1 < \beta < 1$. The functions g_0, g_1 have the following properties.*

- a) g_0 and g_1 are infinitely differentiable on $(0, 1)$.
- b) The function g_0 is positive on $(0, 1)$. The function g_1 is negative on $(0, F_{\alpha\beta}(0))$ and positive on $(F_{\alpha\beta}(0), 1)$. The function

$$\zeta \mapsto c\tau^{-1/\alpha} g_0(\zeta) + \frac{1}{\alpha\tau} g_1(\zeta)$$

is negative on $(0, u^*)$ and positive on $(u^*, 1)$, where $u^* = F_{\alpha\beta}(-c\alpha\tau^{-1/\alpha+1})$.

- c) As $\zeta \downarrow 0$, $g_0(\zeta) = O(\zeta^{1+1/\alpha})$ and $g_0(1 - \zeta) = O(\zeta^{1+1/\alpha})$.
- d) As $\zeta \downarrow 0$, $g_1(\zeta) = -\alpha\zeta + O(\zeta^{1+1/\alpha})$. As $\zeta \uparrow 1$, $g_1(\zeta) = \alpha(1 - \zeta) + O((1 - \zeta)^{1+1/\alpha})$.

- e) The functions g_0 and g_1 can be represented as

$$\begin{aligned} g_0(\zeta) &= \frac{d}{d\zeta} \int_{-\infty}^{F_{\alpha\beta}^{-1}(\zeta)} f_{\alpha\beta}^2(s) ds \\ g_1(\zeta) &= \frac{d}{d\zeta} \int_{-\infty}^{F_{\alpha\beta}^{-1}(\zeta)} s f_{\alpha\beta}^2(s) ds. \end{aligned}$$

Proof. Property a) follows since $f_{\alpha\beta}$ and $F_{\alpha\beta}$ together with its inverse are infinitely differentiable. Property b) is obvious. Properties c) and d) follow from the asymptotic expansions (9) and (11). Finally e) can be checked by differentiation. $\square$

Property e) will not be used in what follows. It should be noted that g_0 and g_1 are of class C^1 on $[0, 1]$, but are not infinitely differentiable at the interval endpoints, except if $\alpha = 1$. Clearly g_0 and g_1 do not depend on c or τ . We are therefore free to form fairly arbitrary linear combinations of g_0 and g_1 by choosing c and τ .

The construction provides travelling wave solutions for (4) for a special class of functions for which $g \in C^1([0, 1])$, $g(0) = g(u^*) = g(1)$ for some $u^* \in (0, 1)$, and $g'(0) < 0$, $g'(u^*) > 0$, $g'(1) < 0$. This raises the possibility that (4) possesses travelling wave solutions for more general functions g with these properties.

If the same construction is attempted for the case $\alpha = 2$, it turns out that g_0 and g_1 are merely continuous on $[0, 1]$, with derivatives that have logarithmic singularities near $\zeta = 0$ and $\zeta = 1$. Therefore the arguments in the next section cannot be extended to the case $\alpha = 2$, and indeed the results of the next section do not hold in that case.

3. RESULTS ON THE SPEED OF SPREAD

This section contains the main results of this paper. As before, the operator A has symbol (5) with $0 < \alpha < 2$ and ρ satisfying (13) with $-1 < \beta < 1$. We always assume that u is a solution of (4) and that $g \in C^1([0, 1], \mathbb{R})$ with $g(0) = g(1) = 0$. Initial data u_0 will be assumed to satisfy

$$(17) \quad u_0 \in C(\mathbb{R}, \mathbb{R}), \quad 0 \leq u_0(x) \leq 1, \quad \lim_{x \rightarrow \infty} u_0(x) = 1, \quad \text{supp}(u_0) \subset [0, \infty).$$

The results in section 4 then imply that (4) has a unique mild solution u that exists for all $x \in \mathbb{R}$, $t > 0$, and this solution satisfies $0 \leq u(x, t) \leq 1$ for all (x, t) . The notation of that section will also be used here.

We first discuss the case where $g \geq 0$ on $(0, 1)$. The main result in this case is the following.

Theorem 3.1. *Let u be the solution of (4) with u_0 satisfying (17).*

a) Let $\alpha > 1$. Assume that $g > 0$ on $(0, 1)$ and that for some $c_0 > 0$, $0 < \gamma < \frac{\alpha}{\alpha-1}$ and all $\zeta \in [0, \frac{1}{2}]$

$$g(\zeta) \geq c_0 \zeta^\gamma.$$

Then for all $c > 0$

$$\liminf_{t \rightarrow \infty} \inf_{x \geq -ct} u(x, t) = 1.$$

b) Let $\alpha = 1$. Assume that $g > 0$ on $(0, 1)$. Then for all $c > 0$

$$\liminf_{t \rightarrow \infty} \inf_{x \geq -ct} u(x, t) = 1.$$

b) Let $\alpha < 1$. Assume that $g \geq 0$ on $(0, 1)$ and $g(\zeta) > 0$ for $\zeta \in [\frac{1-\beta}{2}, 1)$. Then for all $c > 0$

$$\liminf_{t \rightarrow \infty} \inf_{x \geq -ct} u(x, t) = 1.$$

The result shows that the speed of spread is unbounded (that is, (3) holds for all $c > 0$), and it exhibits different mechanisms for this phenomenon. Recall that in the interpretation of [11], the function g is responsible for the growth of a substance whose density is given by u , while A describes the spread of this substance. If $\alpha \in (0, 2)$, the substance spreads with a jump process, not with Brownian diffusion, and jumps of magnitude h occur with a probability that is $O(h^{-\alpha})$ for large h . If $\alpha > 1$, the mean jump distance is still finite. In this case, the growth rate $g(u)$ at small densities (small u) is responsible for the unbounded speed of spread. If α is close to 1, this growth can be very weak ($g(\zeta) \sim \zeta^\gamma$ with large γ), yet the speed of spread is still unbounded. If on the other hand $\alpha < 1$, i.e. jump sizes have unbounded mean, the growth rate for small densities does not matter any more for the speed of spread to be unbounded; in fact there may be no growth at all for small densities ($g(u) = 0$ for small u), and yet the speed of spread is unbounded. In this case, the unbounded speed of spread results from growth that occurs solely for large densities ($g(\zeta) > 0$ only for $\zeta \geq \frac{1-\beta}{2}$). The substance is transported towards $-\infty$ due large ($\alpha < 1$) negative jumps, resulting in an unbounded speed of spread. It is known that in this case, $\frac{1-\beta}{2}$ is the fraction of negative jumps. If this fraction is large, then it is sufficient that growth occurs only for densities close to the maximal value, i.e. $g(u) > 0$ on $[\frac{1-\beta}{2}, 1)$ already implies that the speed of spread is unbounded. The case $\alpha = 1$ is intermediate: Any growth for small densities ($g(\zeta) > 0$ for $\zeta > 0$) results in an unbounded speed of spread.

In the case $\alpha > 1$, it would be interesting to know if the speed of spread is still unbounded if $\gamma \geq \frac{\alpha}{\alpha-1}$ or if a finite speed of spread occurs ((2) holds for large c) if γ becomes sufficiently large, i.e. if growth is extremely weak for small densities u . In the case $\alpha < 1$, it would be interesting to know if a finite speed of spread is possible at all if $g \geq 0$ and g is not identically equal to 0.

The main result in the case where g is negative near $\zeta = 0$ is the following.

Theorem 3.2. *Let u be the solution of (4) with initial data u_0 satisfying (17). Assume that $g'(0) < 0$. Then there exists $c > 0$ such that*

$$\limsup_{t \rightarrow \infty} \sup_{x \leq -ct} u(x, t) = 0.$$

The result shows that negative proportional growth at small densities ($g'(0) < 0$) always limits the speed of spread of a substance whose growth and spread are governed by (4), even for processes whose jump sizes tend to be very large ($\alpha < 1$). I am not aware of an interpretation of (4) in the context of material science, similar to the use of (1) in [1].

The proofs will be given below. The main tools in the proofs are the comparison arguments given in the next section, together with the following auxiliary result.

Lemma 3.1. *Let $g \in C^1([0, 1], \mathbb{R})$ and let g_0, g_1 be defined as in (16), depending on $\alpha \in (0, 2)$, $\beta \in (-1, 1)$.*

a) Let $\alpha \in (1, 2)$. Suppose that $g(\zeta) > 0$ for all $\zeta \in (0, 1]$ and that there exist $c_0 > 0$ and $\gamma < \frac{\alpha}{\alpha-1}$ such that $g(\zeta) \geq c_0 \zeta^\gamma$ for all $\zeta \in [0, \frac{1}{2}]$. Then given any $c > 0$ there exists $\tau > 0$ such that for all $\zeta \in [0, 1]$

$$g(\zeta) \geq c\tau^{-1/\alpha}g_0(\zeta) + (\alpha\tau)^{-1}g_1(\zeta).$$

b) Let $\alpha = 1$. Suppose that $g > 0$ on $(0, 1]$. Then given any $c > 0$ there exists $\tau > 0$ such that for all $\zeta \in [0, 1]$

$$g(\zeta) \geq c\tau^{-1}g_0(\zeta) + \tau^{-1}g_1(\zeta).$$

c) Let $\alpha \in (0, 1)$. Suppose that $g \geq 0$ on $[0, 1]$ and $g(\zeta) > 0$ for all $\zeta \in [\frac{1-\beta}{2}, 1]$. Then given any $c > 0$ there exists $\tau > 0$ such that for all $\zeta \in [0, 1]$

$$g(\zeta) \geq c\tau^{-1/\alpha}g_0(\zeta) + (\alpha\tau)^{-1}g_1(\zeta).$$

d) Suppose $g'(0) < 0$ and $g(\zeta) = 0$ for $\zeta \in [1 - \epsilon, 1]$ for some ϵ . Then there exist $c \in \mathbb{R}$ and $\tau > 0$ such that for all $\zeta \in [0, 1]$

$$g(\zeta) \leq c\tau^{-1/\alpha}g_0(\zeta) + (\alpha\tau)^{-1}g_1(\zeta).$$

Proof. Consider first statement a). Let $\alpha > 1$, $-1 < \beta < 1$ and let $M > 0$ be large enough such that for some $c_1, c_2 > 0$ and all $x \leq -M$

$$F_{\alpha\beta}(x) \geq c_1|x|^{-\alpha}, \quad f_{\alpha\beta}(x) \leq c_2|x|^{-1-\alpha}.$$

This is possible by (11). Let $c > 0$ be given, then we may increase M further such that also

$$c_0 c_1^\gamma M^r \geq c_2 \frac{\alpha-1}{\alpha} c^{\frac{\alpha}{\alpha-1}}.$$

where $r = \frac{\alpha}{\alpha-1} - \gamma > 0$. We omit the subscript $\alpha\beta$ in the formulae involving $F_{\alpha\beta}$ and $f_{\alpha\beta}$ from now on. Now set $\delta = F(-M)$. Then for $0 < \zeta = F(x) \leq \delta$, i.e. $x < -M$, and for all $\tau \geq (M/c)^{\alpha/(\alpha-1)}$

$$\begin{aligned} c\tau^{-1/\alpha}g_0(F(x)) + (\alpha\tau)^{-1}g_1(F(x)) &= \left(c\tau^{-1/\alpha} + (\alpha\tau)^{-1}x\right)f(x) \\ &\leq \frac{\alpha-1}{\alpha}c^{\frac{\alpha}{\alpha-1}}|x|^{1/(1-\alpha)}f(x) \\ &\leq \frac{\alpha-1}{\alpha}c^{\frac{\alpha}{\alpha-1}}|x|^{1/(1-\alpha)}c_2|x|^{-1-\alpha} \\ &= \frac{\alpha-1}{\alpha}c^{\frac{\alpha}{\alpha-1}}c_2|x|^{-\alpha^2/(\alpha-1)} \end{aligned}$$

where a standard calculus argument has been used to see that the expression $(c\tau^{-1/\alpha} + (\alpha\tau)^{-1}x)$ is maximal for $\tau = (|x|/c)^{\alpha/(\alpha-1)}$. We estimate further,

using the choice of M

$$\begin{aligned} c\tau^{-1/\alpha}g_0(F(x)) + (\alpha\tau)^{-1}g_1(F(x)) &\leq c_0c_1^\gamma M^r |x|^{-\alpha^2/(\alpha-1)} \\ &\leq c_0c_1^\gamma |x|^r |x|^{-\alpha^2/(\alpha-1)} = c_0 (c_1|x|^\alpha)^\gamma \\ &\leq c_0 (F(x))^\gamma \leq g(F(x)). \end{aligned}$$

Therefore, for all $\tau \geq (M/c)^{\alpha/(\alpha-1)}$ and all $\zeta < \delta = F(-M)$,

$$c\tau^{-1/\alpha}g_0(\zeta) + (\alpha\tau)^{-1}g_1(\zeta) \leq g(\zeta).$$

Since $g > 0$ on $[\delta, 1]$ by assumption, this inequality can be achieved also on $[\delta, 1]$ by increasing τ even further. This proves part a).

The proof of part b) is straight forward: Given $c > 0$, note that $cg_0(\zeta) + g_1(\zeta) \leq 0$ on the interval $[0, F(-c)]$. Then $\frac{cg_0(\zeta) + g_1(\zeta)}{\tau} \leq g(\zeta)$ is true if τ is sufficiently large.

To prove part c), let again $c > 0$ be given. Let $u^* = \inf\{u \in [0, 1] \mid g(u) > 0\}$. Then $u^* < \frac{1-\beta}{2} = F(0)$. Pick τ large enough such that $F(-c\alpha\tau^{1-1/\alpha}) > u^*$. This is possible since $\alpha < 1$. Then on $[0, u^*]$,

$$c\tau^{-1/\alpha}g_0(\zeta) + (\alpha\tau)^{-1}g_1(\zeta) \leq g(\zeta)$$

since the left hand side is non-positive there by Proposition 2.1. By increasing τ further, we can obtain this estimate also for $\zeta \in [u^*, 1]$, using again that g is assumed to be positive on $[\frac{1-\beta}{2}, 1]$.

To prove part d), note first that

$$c\tau^{-1/\alpha}g_0(\zeta) + (\alpha\tau)^{-1}g_1(\zeta) \geq g(\zeta)$$

on an interval $[0, \delta]$ as soon as $\tau^{-1} + g'(0) > 0$, i.e. for sufficiently small τ . Increasing c sufficiently and noting that $g = 0$ near $\zeta = 1$ extends this inequality to the entire interval $[0, 1]$. $\square$

Proof of Theorem 3.1. The proof uses the same argument for all three parts, so we give details only in part a). Let $\epsilon > 0$. We replace u with $\tilde{u} = (1 + \epsilon)u$ and g with $\tilde{g}$, where $\tilde{g}(\zeta) = (1 + \epsilon)g((1 + \epsilon)^{-1}\zeta)$. Then

$$\partial_t \tilde{u} + A\tilde{u} = \tilde{g}(\tilde{u}).$$

Then $\tilde{g}(\zeta) \geq \tilde{c}_0\zeta^\gamma$ for $\zeta \in [0, \frac{1}{2}]$, possibly with a changed c_0 , and additionally $\tilde{g} > 0$ on $(0, 1]$. Let $c > 0$ be given, then there exists $\tau > 0$ such that

$$(18) \quad \tilde{g}(\zeta) \geq (c + 1)\tau^{-1/\alpha}g_0(\zeta) + (\alpha\tau)^{-1}g_1(\zeta).$$

for all $\zeta \in [0, 1]$ by Lemma 3.1. By extending g_0 and g_1 to be zero on $[1, 1 + \epsilon]$, this inequality is true on $[0, 1 + \epsilon]$. Now find a constant d such that $v_0(x) = H(x - d) \leq \tilde{u}(x, 0)$ for all x . This is possible since $\lim_{x \rightarrow \infty} \tilde{u}(x, 0) = 1 + \epsilon$. By Proposition 4.3, we see that

$$\tilde{u}(x, t) \geq F\left((x - d)t^{-1/\alpha}\right)$$

for all $x \in \mathbb{R}$, $t > 0$. This is in particular true for $t = \tau$. Now use Proposition 4.1 and (18) to infer that

$$\tilde{u}(x, t) \geq F\left((x - d + (c + 1)t)\tau^{-1/\alpha}\right)$$

for all $x \in \mathbb{R}$, $t \geq \tau$. Therefore for $t \geq \tau$ and $x \geq -ct$,

$$\begin{aligned} \tilde{u}(x, t) &\geq F\left((x - d + (c + 1)t)\tau^{-1/\alpha}\right) \\ &\geq F\left((-ct - d + (c + 1)t)\tau^{-1/\alpha}\right) \\ &= F\left((t - d)\tau^{-1/\alpha}\right). \end{aligned}$$

As $t \rightarrow \infty$, the right hand side goes to 1. Rewriting this in terms of u , we see that

$$\liminf_{t \rightarrow \infty} \inf_{x \geq -ct} \tilde{u}(x, t) \geq (1 + \epsilon)^{-1}.$$

Since ϵ was arbitrary, the desired result follows.

In case of part b), the same argument can be used without changes, appealing to part b) of Lemma 3.1.

In case of part c), we have to restrict ϵ such that $\tilde{g} > 0$ on $[\frac{1-\beta}{2}, 1]$, that is, $g > 0$ on $[\frac{1-\beta}{2(1+\epsilon)}, 1]$. The rest of the proof is again unchanged, using part c) of Lemma 3.1. $\square$

Proof of Theorem 3.2. We replace u with $\tilde{u} = \frac{1}{2}u$ and g with $\tilde{g}$, where $\tilde{g}(\zeta) = \frac{1}{2}g(2\zeta)$ for $0 \leq \zeta \leq \frac{1}{2}$ and $\tilde{g}(\zeta) = 0$ for $\zeta \in (\frac{1}{2}, 1]$. Then $\tilde{g}'(0) = g'(0) < 0$ and

$$\partial_t \tilde{u} + A\tilde{u} = \tilde{g}(\tilde{u}).$$

By Lemma 3.1, part d), there exist $c > 0$ and $\tau > 0$ such that

$$\tilde{g}(\zeta) \leq (c - 1)\tau^{-1/\alpha}g_0(\zeta) + (\alpha\tau)^{-1}g_1(\zeta).$$

Since $\lim_{x \rightarrow \infty} \tilde{u}(x, 0) = \frac{1}{2}$ and $u(x, 0) = 0$ for $x < 0$, we can find $d > 0$ such that $F(x + d)\tau^{-1/\alpha} \geq \tilde{u}(x, 0)$ for all $x \in \mathbb{R}$. Using Proposition 4.1, one sees that

$$F\left((x + d + (c - 1)t)\tau^{-1/\alpha}\right) \geq \tilde{u}(x, t)$$

for all $x \in \mathbb{R}$, $t > 0$. Therefore for $t > 0$ and $x \leq -ct$,

$$\begin{aligned} \tilde{u}(x, t) &\leq F\left((x + d + (c - 1)t)\tau^{-1/\alpha}\right) \\ &\leq F\left((-ct + d + (c - 1)t)\tau^{-1/\alpha}\right) \\ &= F\left((-t + d)\tau^{-1/\alpha}\right). \end{aligned}$$

The right hand side tends to 0 as $t \rightarrow \infty$. In terms of u , this implies

$$\limsup_{t \rightarrow \infty} \sup_{x \leq -ct} u(x, t) = 0.$$

This concludes the proof. $\square$

4. FACTS ABOUT FRACTIONAL REACTION-DIFFUSION EQUATIONS

In this section we summarize some basic theory about (4) that is needed in this note. A broader and deeper discussion may be found in [3].

We work in the Banach space

$$\mathcal{C}_{lim} = \{w \in C(\mathbb{R}) \mid \lim_{x \rightarrow \infty} w(x) \text{ and } \lim_{x \rightarrow -\infty} w(x) \text{ exist}\}$$

equipped with the supremum norm $\|\cdot\|$. Let A be the pseudodifferential operator with symbol (5) and parameters α, ρ . As always, let ρ, β be related by (13) and $-1 < \beta < 1$. Solutions of the free equation (12) with initial data $u(\cdot, 0) = \varphi \in \mathcal{C}_{lim}$ then can be written in terms of the fundamental solution $(x, t) \mapsto t^{-1/\alpha} f_{\alpha\beta}\left(\frac{x-y}{t^{1/\alpha}}\right)$, namely

$$(19) \quad u(x, t) = \int_{\mathbb{R}} t^{-1/\alpha} f_{\alpha\beta}\left(\frac{x-y}{t^{1/\alpha}}\right) \varphi(y) dy$$

where $f_{\alpha\beta}$ is a stable probability density function.

For fixed α and ρ and $\varphi \in \mathcal{C}_{lim}$, define

$$S(t)\varphi(x) = u(x, t)$$

where u is given by (19). This is a positive C_0 semigroup on $\mathcal{C}_{lim}$ and a Feller semigroup on the subspace of functions in $\mathcal{C}_{lim}$ that vanish at $\pm\infty$. If ψ is a continuous function from $[0, T]$ to $\mathcal{C}_{lim}$, then solutions of the inhomogeneous equation

$$(20) \quad \partial_t u(x, t) + Au(x, t) = \psi(x, t), \quad u(\cdot, 0) = \varphi$$

can be written with the variation-of-constants formula

$$(21) \quad u(\cdot, t) = S(t)\varphi + \int_0^t S(t-s)\psi(\cdot, s) ds.$$

A continuous curve $u : [0, T] \rightarrow \mathcal{C}_{lim}$ that satisfies (21) is commonly called a mild solution of (20). Next let $g : [0, \infty) \times \mathbb{R} \rightarrow \mathbb{R}$ be locally Lipschitz continuous in both variables and let $\varphi \in \mathcal{C}_{lim}$. Then the equation $\partial_t u(x, t) + Au(x, t) = g(t, u(x, t))$ (for which (4) is a special case) has a unique mild solution $u \in C([0, T], \mathcal{C}_{lim})$, where $0 < T \leq \infty$ is maximal. Either $T = \infty$, or $\|u(\cdot, t)\| \rightarrow \infty$ as $t \uparrow T$. The solution can be obtained as the locally in time uniform limit of the iteration scheme

$$u_{n+1}(\cdot, t) = S(t)\varphi + \int_0^t S(t-s)g(s, u_n(\cdot, s)) ds \quad (n = 0, 1, \dots)$$

with u_0 arbitrary, e.g. $u_0(\cdot, t) = S(t)\varphi$. It is possible to set up a more general solution theory, but this is not needed for the purposes of this paper.

Solutions of (4) satisfy comparison theorems. Results of this type are true for all Feller semigroup. A systematic study of such semigroups and their generators was carried out in [5], following the seminal work on this topic in [18]. For the sake of completeness, a comparison result is stated here, and its proof is sketched.

Proposition 4.1. *Let $u, v \in C([0, T], \mathcal{C}_{lim})$ be mild solutions of the equations*

$$\partial_t u + Au = g(u), \quad \partial_t v + Av = h(v)$$

where $g, h : \mathbb{R} \rightarrow \mathbb{R}$ are locally Lipschitz continuous. If

$$g(\zeta) \leq h(\zeta) \quad \forall \zeta \in \mathbb{R}$$

and

$$u(\cdot, 0) \leq v(\cdot, 0)$$

then

$$u(x, t) \leq v(x, t) \quad \forall (x, t) \in \mathbb{R} \times [0, T].$$

Proof. Let $M = \max_{[0, T]} (\|u(\cdot, t)\| + \|v(\cdot, t)\| + 1)$. Let $\lambda > |g'(\zeta)| + |h'(\zeta)|$ for all $|\zeta| \leq M$. Without loss of generality we may assume that g and h are constant outside $[-M, M]$. Set

$$U(x, t) = e^{\lambda t} u(x, t), \quad V(x, t) = e^{\lambda t} v(x, t)$$

and observe that U and V satisfy

$$\begin{aligned} \partial_t U + AU &= \tilde{g}(t, U) \\ \partial_t V + AV &= \tilde{h}(t, V) \end{aligned}$$

with $\tilde{g}(t, \zeta) = \lambda \zeta + e^{\lambda t} g(e^{-\lambda t} \zeta)$ and $\tilde{h}(t, \zeta)$ defined similarly. Clearly, $\tilde{g}(t, \zeta) \leq \tilde{h}(t, \zeta)$ for all ζ . The function $\tilde{g}$ is non-decreasing in its second argument, since for almost all ζ

$$\partial_\zeta \tilde{g}(t, \zeta) = \lambda + g'(e^{-\lambda t} \zeta) \geq 0.$$

Consider the iteration scheme

$$U_{n+1}(\cdot, t) = S(t)u(\cdot, 0) + \int_0^t S(t-s)\tilde{g}(s, U_n(\cdot, s)) ds$$

and similarly for V_n and $\tilde{h}$. The scheme for the U_n converges to the limit U , and the scheme for the V_n converges to the limit V .

We now employ a standard induction argument to show that $U_n \leq V_n$ on $\mathbb{R} \times [0, T]$ for all n . This implies that $U \leq V$ and therefore also $u \leq v$ on $\mathbb{R} \times [0, T]$. Let $U_0(\cdot, t) = S(t)u(\cdot, 0)$ and $V_0(\cdot, t) = S(t)v(\cdot, 0)$, then $U_0 \leq V_0$ on $\mathbb{R} \times [0, T]$ since S is a positive semigroup and $u(\cdot, 0) \leq v(\cdot, 0)$. Suppose

$U_n \leq V_n$ on $\mathbb{R} \times [0, T]$, then

$$\begin{aligned}
U_{n+1}(\cdot, t) &= S(t)u(\cdot, 0) + \int_0^t S(t-s)\tilde{g}(s, U_n(\cdot, s))ds \\
&\leq S(t)v(\cdot, 0) + \int_0^t S(t-s)\tilde{g}(s, U_n(\cdot, s))ds \\
&\leq S(t)v(\cdot, 0) + \int_0^t S(t-s)\tilde{g}(s, V_n(\cdot, s))ds \\
&\leq S(t)v(\cdot, 0) + \int_0^t S(t-s)\tilde{h}(s, V_n(\cdot, s))ds \\
&= V_{n+1}(\cdot, t)
\end{aligned}$$

which completes the induction step. This proves the proposition. $\square$

Corollary 4.2. *Consider a mild solution $u \in C([0, T], \mathcal{C}_{lim})$ of (4) and assume that g is locally Lipschitz continuous. If $g(\gamma) \geq 0$ for some γ and $u(\cdot, 0) \geq \gamma$, then $u(\cdot, t) \geq \gamma$ for all t . If $g(\gamma) \geq 0 \geq g(\delta)$ for some $\gamma < \delta$ and $\gamma \leq u(\cdot, 0) \leq \delta$, then $\gamma \leq u(\cdot, t) \leq \delta$ for all t , and the solution can be continued to $\mathbb{R} \times [0, \infty)$.*

The proof consists in observing that the constant functions $v(x, t) = \gamma$ and $w(x, t) = \delta$ solve (4) with right hand sides 0 and therefore must be pointwise bounds for the solution, by Proposition 4.1. If the solution remains bounded between two constants, then its supremum norm remains bounded and it can be continued to $\mathbb{R} \times [0, \infty)$.

Also required is a comparison result for solutions whose initial data are step functions. Since such initial data are not in $\mathcal{C}_{lim}$, a separate argument is required.

Proposition 4.3. *Let $u \in C([0, T], \mathcal{C}_{lim})$ be a mild solution of (4), with locally Lipschitz continuous g . Assume that*

$$u(x, 0) \geq v_0(x) = a_0 + \sum_{j=1}^N a_j H(x - c_j) \quad \forall x \in \mathbb{R}$$

where $a_j \in \mathbb{R}$, $c_1 < c_2 < \dots < c_N$, and H is the Heaviside function. Let $\gamma = \min_{\mathbb{R}} v_0(x)$ and $\delta = \max_{\mathbb{R}} v_0(x)$. Assume also that $g \geq 0$ on $[\gamma, \delta]$. Then

$$(22) \quad u(x, t) \geq a_0 + \sum_{j=1}^N a_j F_{\alpha\beta} \left(\frac{x - c_j}{t^{1/\alpha}} \right) \quad \forall x \in \mathbb{R}, 0 < t \leq T$$

where $F_{\alpha\beta}$ is the cumulative distribution function of the associated stable distribution.

Proof. We know that $u(x, t) \geq \gamma$ and thus may assume that $g(\zeta) \geq 0$ also for $\zeta < \gamma$. For arbitrary $\epsilon\sigma > 0$, we set

$$v_{\epsilon\sigma}(x) = \frac{1}{\sigma} \int_0^\sigma v_0(x-z)dz - \epsilon.$$

Then $v_{\epsilon\sigma}$ is piecewise linear and constant outside the interval $[c_1, c_N + \sigma]$; in particular, $v_{\epsilon\sigma} \in \mathcal{C}_{lim}$. Solving (12) with initial data $v_{\epsilon,\sigma}$ gives the solution

$$V_{\epsilon\sigma}(x, t) = \frac{1}{\sigma} \int_0^\sigma \sum_{j=1}^N a_j F_{\alpha\beta} \left(\frac{x-z-c_j}{t^{1/\alpha}} \right) + a_0 - \epsilon.$$

Given $\epsilon > 0$, it is possible to find $\sigma > 0$ such that $v_{\epsilon\sigma} < u_0(x)$ on $\mathbb{R}$, since u_0 is uniformly continuous. Clearly, $\gamma - \epsilon \leq V_{\epsilon\sigma} \leq \delta$. We may therefore view $V_{\epsilon\sigma}$ as a solution of (4) with a right hand side h that satisfies $h(\zeta) = 0 \leq g(\zeta)$ for $\zeta \leq \delta$ and $h(\zeta) \leq g(\zeta)$ also for $\zeta > \delta$. Then by Proposition 4.1

$$u(x, t) \geq V_{\epsilon,\sigma}(x, t) \quad \forall x \in \mathbb{R}, 0 < t \leq T.$$

Send δ to 0, then since $F_{\alpha\beta}$ is uniformly continuous, (22) is obtained with a_0 replaced by $a_0 - \epsilon$ on the right hand side. Now send ϵ to 0 and (22) follows. $\square$
